

A METHOD AND APPARATUS FOR DETECTING  
 LAMENESS IN ANIMALS  
 This application claims the benefit of provisional application No. 60/207,823  
 filed 5/30/00.  
 BACKGROUND OF INVENTION

11 application was  
filed 5/30/00.  
BACKGROUND

This invention relates to a new method and apparatus for detecting lameness in animals and promoting animal well-being. The preferred embodiment of this invention is for detecting lameness in four legged animals, such as but not limited to horses, dairy cows, non-dairy cows, pigs, and sheep.

Dairy production is an important industry in the U.S. and a major branch of agriculture in many countries around the world. Cow lameness caused by hoof and leg ailments is a costly problem for the dairy farmer. Lameness necessitates medical treatment, reduces milk production, results in decreased body condition, impairs reproduction performance, and adversely impacts the social status of animals. Economically, lameness is reported to be the third most costly problem for dairy herds following mastitis and sub-fertility. The average cost of lameness is reported to be 412 dollars per incident and the annual incidence rate in the U.S. is fifteen percent. Thus, the annual economic losses due to lameness is over 570 million dollars for the over nine million U.S. cows. These losses significantly impair dairy farms and harm the entire bovine industry.

In addition to the economic impact, lameness is also recognized as an important animal welfare issue. The 1993-94 Annual Report of the Animal Welfare Foundation of the British Veterinary Association states that "... if it were possible to substantially reduce the incidence of lameness, this single initiative, more than any other would benefit more animals than any other (initiative) ...." Thus, researchers have focused on developing a means of detecting hoof and leg ailments at their early onset.

Lameness in dairy herds has been reported to be a critical economic factor and a vital animal-welfare issue for the dairy industry around the world. Various lameness evaluation schemes that assess the severity of the ailment, using non-clinical personal, have been suggested.

These schemes are based on visual observations of individual cattle. In one scheme, lameness scoring is based on the shape of the cow's back both as the animal stands and as the animal walks. However, although this scheme lends itself to field use, its results are highly subjective and are non-quantitative in nature.

There are reports of management programs to control lameness and studies of the housing factors that influence the locomotion of dairy cows. Some of the etiological factors contributing to lameness are nutrition, bacterial and fungal infections, bacterial endotoxin, environmental conditions, housing, flooring, feeding management, and cow behaviors. The fact that many different factors lead to lameness makes it almost impossible to eliminate hoof and leg ailments and imposes difficulties for diagnostic procedures. Early detection of hoof and leg ailments is not a yet reality and most farmers record an incidence of lameness only at the stage when the cow is crippled. Thus, there is a need in the art for a method and an apparatus able to provide early detection of hoof and leg problems, which will enable prompt veterinarian medical intervention to reduce economic losses, lessen the pain that the animal endures, and expedite the animal's recovery process. Furthermore, an early detection system will facilitate scientific testing of management programs designed to reduce the rate of incidence of lameness in dairy herds and will promote animal well-being.

A research effort that analyzes the gait of horses and detects lame limbs is reported in Schamhardt, H.C. and Merckens, H.W., "Objective determination of ground contact of equine limbs at the walk and trot: comparison between ground reaction forces, accelerometer data and kinematics," *Equine Vet. J Suppl.* No. 17, pp. 75-79, 1994. In this study, the animal is led over a single force plate and a Horse ("H") index is calculated. However, this method and apparatus only detected the force of one of the animal's limbs. To obtain forces from each of the animal's limbs, four separate tests would have to be performed. Therefore, even though a set of forces could be obtained for each limb, such data was merely a compilation of four or more separate tests wherein the speed of the animal, as well as other variables, varied in each run. To detect lameness, the H value is compared with a previously calculated sound horse model. This type of

system and index are not available for detecting lameness in dairy cows and they are not as sensitive and versatile as the system described herein. In particular, the H index relies on leading a horse multiple times across a measuring device under the assumption that the speed of the horse remains constant during all measurements.

## SUMMARY OF INVENTION

This invention relates to a method and apparatus for detecting lameness in animals and for promoting animal well-being, wherein one or more force places are configured to detect forces generated by an animal and these forces are utilized to determine the soundness of an animal.

Additional advantages and other features of the present invention will be set forth in part in the description which follows and in part will become apparent to those having ordinary skill in the art upon examination of the following or may be learned from the practice of the invention. The advantages of the invention may be realized and obtained as particularly pointed out in the appended claims.

In one aspect, the invention comprises a computer-based diagnostic system to detect and analyze ground reaction forces produced by an animal passing through the diagnostic system, comprising a first plate and a second plate disposed adjacent the first plate. A first plurality of load cells is also provided, wherein each of the first plurality of load cells is configured to detect a force applied to the first plate along at least one axis and output at least one signal representative of the detected force. Similarly, a second plurality of load cells is provided, wherein each of the second plurality of load cells is configured to detect a force applied to the second plate along at least one axis and output at least one signal representative of the detected force. A processor adapted to execute at least one force analysis instruction set is provided to, in combination with the force analysis instruction set, receive signals output from the first and second plurality of load cells and calculate a magnitude and location of a force applied to each of

floor plate and comparing the calculated forces to a range of forces indicative of at least one of a sound animal condition, an indeterminate animal condition, or a lame animal condition.

#### BRIEF DESCRIPTION OF THE FIGURES

Figure 1(a) is a schematic representation of Reaction Force Detection (RFD) system of the present invention showing a partial side view of the RFD system including a step up, force-detecting floor plates, and ramp down.

Figure 1(b) is an isometric view of a force plate used in the present invention and an applied load.

Figure 1(c) is a top down view of the RFD system including a step up, force-detecting floor plates, and ramp down of the present invention.

Figures 2(i)-2(iv) are graphs depicting the load cell reactions of the left and right plates plotted as a function of time ((i) and (ii)), the animal's walkthrough speed as measured by a photo cell array (iii), and the animal's body weight calculated by summing the load cell reactions (iv).

Figures 3(i)-3(iv) are charts showing the accuracy of body weight measurements, wherein Figures 3(i) and 3(ii) illustrate weight readings of the left and right plate when a weight of 203.8 Kg is placed at five points along the line  $X=18.4$  cm and the percentage errors of these measurements for the left and right plates in Figures 3(iii) and 3(iv), respectively.

Figures 4(i)-4(vi) are graphs illustrating a typical time history of X (Figures 4(i) and 4(ii)) and Y (Figures 4(iii) and 4(iv)) coordinates of the cow's limb positions when passing through the RFD unit. Corresponding ground reaction forces are depicted in Figures 4(v) and 4(vi).

Figures 5(i)-5(iv) are graphs showing the accuracy of the X and Y coordinates of the limb positions.

Figures 6(i)-6(iv) are graphs showing the time history of the Y coordinate of a sound cow's limb positions on the left and right plates (Figures 6(i) and 6(ii), respectively) and the corresponding normalized ground reaction forces (GRF)(Figures 6(iii) and 6(iv), respectively) obtained by dividing the GRF by the animal's body weight.

Figures 7(i)-7(iv) are graphs showing the time history of the Y coordinate of a lame cow's limb positions on the left and right plates (Figures 7(i) and 7(ii), respectively) and the corresponding normalized ground reaction forces (Figures 7(iii) and 7(iv), respectively).

Figures 8(a)-8(f) are graphs showing the Y-positions of the limbs on the left plate (a) and right plate (b), as well as the distributions of an equivalent GRF for two-limb conditions (c and d) and distributions of equivalent GRF to individual limbs (e and f).

Figures 9(a)-9(d) are bar charts showing normalized peak ground reaction force (PGRF) for sound cows and for lame cows (Figures 9(a) and 9(b), respectively) and Symmetry Factors of sound cows and lame cows.

Figure 10 depicts a computer-based system upon which the invention may be implemented.

Figure 11 illustrates limb movement variables of individual limbs of two sound cows calculated in accord with the apparatus and method of the invention.

Figure 12 illustrates limb movement variables of individual limbs of two lame cows calculated in accord with the apparatus and method of the invention.

## DETAILED DESCRIPTION OF THE INVENTION

The Reaction Force Device (RFD) system 100 measures, among many other variables, the weight and forces related to walking gait of animals. The RFD system 100 has a walk-through layout configured to guide the animals through the RFD one at a time. As the animal passes through the RFD system, stepping on instrumented plates, the animal's limb reaction forces, weight, bilateral symmetry of limb reaction forces, and other factors may be determined, as discussed below. Once one animal has passed through the RFD system, another animal may then enter the RFD system. Thus, the RFD system is particularly suited to applications wherein a plurality of animals, such as a herd of cattle, are sequentially enter the system to determine the presence of lameness in any particular individual in the group.

109040-112300

To facilitate sequential movement of a plurality of animals, impediments to animal movement may be provided. In a preferred aspect of the invention, impediments include an initial step-up 110, side railings 115 (shown only on one of two sides in Figure 1(a)) or side walls that constrain the animal's lateral movement to thereby force the animal to walk over the plate, and a divider 125 that prompts the animal to place its left leg on a left plate 130 and right foot on a right plate 120 or prevents the animal from placing its left leg on a left plate 130 and right foot on a right plate 120. In a preferred aspect, the step-up 110 dimensions are 127 cm x 122 cm x 18 cm (width, length and height), although these dimensions may be freely varied to accomplish the intended result. The step-up 110 is configured to compel the animals to space themselves and walk through the system one at a time.

Following the step-up 110, animals moving through the RFD system next encounter a floor comprising parallel left and right portions or plates 130, 120 separated by a divider or partition 125 projecting upwardly from a position between the left and right plates, as shown in Figures 1(a) through 1(c). In a preferred aspect, the left and right floor plates 130, 120 are each made of three layers comprising a 3/16" steel floor grating covered with 1/8" sheet steel and a top surface comprising an anti-slip, corrosion-resistant flooring. The gratings may be, for example, SGW gratings manufactured by McNichols Corporation of Tampa, Florida and the anti-slip flooring may be 1/8" Chemplate made by Chemgrate Corporation of Woodinville, WA.

In a preferred aspect, such as for a bovine application, each plate 130, 120 is 63 cm in width and 198 cm in length, as shown in the central portion of Figure 1(a). As illustrated in Figure 1(a), divider 125 is approximately 1 cm in width, yielding the total width of 127 cm. In an application of the RFD system to horses, for example, it is generally desirable to have a force plate length of between about 300 and 500 cm, although longer force plate lengths could certainly be utilized. It has been determined, however, that if the plate is too small, such as 36 cm x 52 cm, data collection of the ground reaction forces (GRFs) for bovines and animals of like gait becomes increasingly difficult, necessitating multiple passes through the system to obtain GRFs for all limbs. Therefore, although the size and number of the plates may be varied in

accord with the invention, such variation must permit measurement of the GRFs for all four of the animals limbs in a single pass of the animal through the RFD. This may be accomplished, for example, by sampling the walking gait or other gait such as a trot or run, of a sample population of the animals and determining the distance traversed by the animals at that gait to a desired statistical significance. In one aspect of the invention, it is preferred to use a length inclusive of at least 3 of the distance traversed by the sample population at the desired gait. In another aspect of the invention, the above length is multiplied by a factor such as two, three, or more to obtain multiples of individual limb contact data with the first and second plates 130, 120. Additionally, more than two plates 130, 120 may be used in accord with the invention. For example, another set of plates, a second left plate and a second right plate, could be provided after the first left plate 130 and first right plate 120. Alternatively, prior to or subsequent to the initial plates 130, 120, a fore force plate and a hind force plate could be provided to detect differences in an animal's stance and force distribution between fore limbs and rear limbs.

Partition or divider 125 projects upwardly from an inner edge of one of the left and right plates 130, 120 or a position between the left and right plates. This divider 125, in a preferred aspect of the invention, is a single continuous divider having a width of about 1 cm and a height of between about 0.5 to 1.5 cm. The width and the height may vary in accord with a size of the animal, but is preferred not to exceed a height of about 3 cm. The inventors have determined that barrier 125 heights above 3 cm start to affect the animal's normal cadence, thus potentially reducing the amount of or value of the data obtained. However, in accord with the invention, the height of barrier 125 may exceed 3 cm if the specific data desired to be obtained is not related to or dependent on the animal's cadence and limb cross-over is itself a concern. In a preferred embodiment of the divider 125 may comprise a rigid or semi-rigid material, such as a plastic or resilient rubber, and may preferably be rounded at the edges. A partition or divider 125 is not required, however, as limb-cross over is uncommon and may be corrected by an additional run of the animal through the RFD or by intervention by the RFD user in the data analysis to back out the values of the left limb and right limb, respectively.

As shown by the embodiment of Figure 1(c), each plate 130, 120 is supported by an array of four load cells 150 distributed adjacent the four corners of the respective plate 130, 120. However, this is merely a preferred aspect of the invention. The invention may comprise more or less load cells 150 distributed in various locations and arrangements above, below, or adjacent the plates 130, 120 in accord with the physical configuration and type (e.g., number of axes) of load cell selected and the desired robustness of data.

These load cells 150 measure the ground reaction forces (GRFs) produced as the animal steps on each plate. The RFD system 100 measures these ground reaction forces and calculates the position of the weight placed on the respective floor plate 130, 120. As illustrated in Figure 1(c), each of the plates 130, 120 comprises a separate coordinate system defined by  $(X_L, Y_L)$  and  $(X_R, Y_R)$ , wherein  $(X_{L,R}, Y_{L,R}) = (0 \text{ cm}, 0 \text{ cm})$  is arbitrarily located at the innermost corner of each of the plates 130, 120. In a preferred orientation of the working axes, X is positive in a direction toward the outside of the plates, Y is positive in a direction of the rear or backside of the plates, and Z is positive in an upward direction. The position of a force applied to the plates 130, 120 is thus defined through the left and right coordinate systems  $(X_L, Y_L)$  and  $(X_R, Y_R)$  shown Figures 1(a) and 1(c). When a single limb (i.e., hoof or foot) is on a plate 130, 120, the RFD system 100 calculates the position of that limb. When more than one limb is in contact with a floor plate 130, 120, the RFD system 100 calculates the position of an equivalent or resultant force, as discussed below.

A suitable load cell for this arrangement is Model RL35083 produced by Rice Lake Weighing Systems of Rice Lake, Wisconsin. If a greater or lesser number of load cells 150 is desired, correspondingly and respectively decreasing or increasing the Ground Reaction Force (GRF) experienced by any individual load cell 150, alternative load cells may be selected to appropriately maintain the GRFs within the calibrated working ranges of each load cell. For applications involving cows, the inventors have determined that the GRFs are substantially vertical and GRF variations due to lameness, or the onset thereof, are determinable based on differences in these vertical GRFs. Therefore, bovine applications may employ a plurality of

single-axis load cells measuring force in only the vertical direction, thus achieving a significant cost reduction over comparable multi-axis system.

However, the present invention also includes applications utilizing multi-axis load cells such as 2-axis, 3-axis, and n-axis load cells, where n is any integer, in any number and any combination. For example, a lesser number of multi-axis load cells 150 could be used in lieu of the four single-axis load cells of the embodiment described above for a bovine application. Alternatively, an equal number or greater number of such multi-axis load cells could be used, just as the number of single-axis load cells could be increased, as desired. Some embodiments of the present invention could, for example, advantageously utilize one or more load cells 150 per left or right plate 130, 120, wherein the load cell 150 is able to measure three orthogonal force components along the X, Y, and Z axes, as well as the moments about the axes, producing up to six outputs. These multi-axis load cells are particularly useful for measuring GRF components of hoof or foot movement in a plurality of axis, but may be also used to reduce the number of load cells required for an RFD, such as an RFD configured for a bovine application, by replacing the 4 single-axis load cells with two 3-axis load cells for each of the left and right plates 130, 120. Thus, in accord with the invention, the load cell 150 specifications and arrangements may be freely varied and optimized to identify ailments endemic to a particular animal type based on the physical manifestation of such ailment on the GRFs produced by the animal's hoof or foot against a load sensitive surface 130, 120.

In the above described aspect of the invention, the load cells 150 and left and right plates 130, 120 are mounted on a single base. As shown in Figure 9, discussed in more detail below, the load cell 150 outputs are sampled by an A/D board 950, such as an Iotech DaqBook model 200, receiving signals from an external eight channel strain gage module 970, such as an Iotech DBK43A. These eight channels are read sequentially through a single channel amplifier 960 and the sampled data is stored in computer memory 906, 910 in a convenient computer readable medium, such as an ASCII file. The sampling rate of the A/D board is preferably set to 100 Hz, but may be increased in accord with frequency of the sampled events to provide an appropriate

sampling rate, such as a sampling rate greater than the Nyquist rate, as known to those skilled in the art.

Following passage of the animal over the step-up 110 and over the left and right plates 130, 120, a ramp down 140 is disposed immediately after the left and right plates to permit egress of the animal from the RFD system 100. A suitable ramp down possesses a width of 127 cm and a length of 122 cm, although these dimensions may vary significantly in accord with space constraints, if any. Generally, the downgrade is maintained between about 5 to 15° to avoid injury to the animals. The ramp 140 preferably comprises the same layered structure as the left and right floor plates 130, 120. Alternatively, some animals, such as horses do not respond well to such ramps, steps, or height differences. Therefore, another embodiment of the invention advantageously incorporates the left and right floor plates 130, 120 into the floor itself so that the upper surface of the floor plates 130, 120 are substantially flush with the remainder of the floor surface.

A plurality of photocells, and corresponding reflective elements, may be disposed to measure each animals' speed through the RFD system 100. In one preferred aspect, illustrated in Figure 1(c), three photocells 160 are sequentially arranged along the left or right plates 130, 120 so as to be triggered by the cow's brisket and rear flank as the cow passes through the line of sight of one of the three sequentially spaced photo-cells. Any number of photocells could be used in accord with the invention, however. Additionally, it is generally preferred that the photocells 160 be spaced along the entire length of the plates 130, 120, or may be grouped toward the center or toward one side in accord with the invention. Moreover, other devices commonly used to determine the speed of an object, such as but not limited to those using optics or light signals, such as laser pulse systems determining velocity using time-of-flight or phase shift techniques, or acoustically-based speed sensing devices may also be used.

The RFD system 100 is calibrated by placing a known or calibrated weight at predetermined (X, Y) positions along each of the left and right plates 130, 120 and recording the

voltage produced by the individual load cells 150. In a preferred calibration technique, a calibrated load of 203.8 Kg is placed at  $(X, Y) = (18.74 \text{ cm}, 99 \text{ cm})$ .

Initial animal tests showed that a sound cow places her limbs at X values that range between 15 to 20 cm when passing through the RFD system 100. Accordingly, a longitudinal center line at  $X = 18.74 \text{ cm}$  was selected as a preferred calibration point, however, any point between 15 cm and 20 cm would suffice for this application. Correspondingly, the weight of the calibration weight and the location of the center line may be adjusted in accord with the size and weight of the group of animals to be observed. The system calibration points, shown as  $C_L$  and  $C_R$  in Figure 1(c), are selected along the longitudinal center lines at  $X_{L,R} = 18.74 \text{ cm}$ . To calibrate the system, it is preferred that three calibrated weights be placed on each of the left and right plates 130, 120 at the designated calibration points to provide a known force in the negative Z direction and readings of each of the load cells 150 are measured and stored. In one aspect, the weights may be 113.2 kg, 158.6 kg, and 203.8 kg.

The reaction forces at each of the eight load cells 150 is evaluated, in one preferred aspect of the invention, via one or more finite element models (FEM), known to those skilled in the art, when the unit loads are applied at the left and right calibration points  $C_L$  and  $C_R$ . Alternative calculation methods known to those skilled in the art may also be used to determine the reaction forces. Lines that pass through the zero load conditions and best fit, using conventional best fit techniques, to the three applied known loads establish the loading factors of the eight individual load cells 150. In other words, the calibration factors of the load cells 150 are calculated as a ratio of the computed applied loads to the individual load cell 150 readings. These factors, listed in Table 1 below, are stored computer 900 for later use by the calibration program. It is preferred that the calibration procedure be performed prior to use of the RFD; however, trending analyses may advantageously be performed to determine the degree of miscalibration over time for a particular application and environment to determine the efficacy of such per-use calibrations.

Table 1. Load distribution of the right and left floor plates as calculated by the finite element model and corresponding calibration factors of the system eight load cells.

Load Cell	Load Distribution Obtained by FEM	Calibration Factors Kg/Volt
LC1	0.08	0.0257
LC2	0.06	0.0111
LC3	0.44	0.0324
LC4	0.42	0.0273
LC5	0.44	0.0264
LC6	0.43	0.0260
LC7	0.07	0.0229
LC8	0.06	0.0286

To characterize the accuracy of the measurements of the ground reaction forces and total body weight measurements, a weight of 203.8 kg is placed at five points along the lines  $X_{L,R} = 18.74$  cm. Each measured load and its location is measured and calculated, respectively, in a manner discussed below. Errors of the load measurements on the right and left plates have been found to be less than 1.3% and 1.7%, respectively, as shown in Figure 3(iv) and 3(iii), respectively. The resulting error locations along the X and Y axes in the right plate 120 were found to be less than 1.3 and 3.1 cm, respectively, and the corresponding errors in the left plate 130 are less than 1.5 and 2.4 cm, respectively.

In the RFD system 100, load cell 150 reactions to the cow's passage are recorded as a function of time (see Figures 2(i) and 2(ii)) while the aforementioned array of photocells 160 measures the walkthrough speed (Figure 2(iii)). Summation of load cell 150 reactions provides an accurate measurement of the cow's body weight. As shown in Figure 2(iv), for example, the body weight of cow 18 is determined to be 672.7 Kg.

Turning to the calculations executed by the computer 900 in the analysis of the animal's walking gait and weight, the load cell 150 reactions are used to calculate the X and Y coordinates

of the cow's limb positions and the associated left and right Ground Reaction Forces (GRF), previously mentioned. In these calculations, it is assumed that the right and left legs of the cow make contact with the corresponding right and left plates 130, 120 without crossover, and that a single limb is in contact with each of the right and left plates. However, when two legs are detected on a plate 130, 120, the position of an equivalent reaction force is calculated. This equivalent force is analogous to the center of gravity of the left and right sides of the animal. The Reaction Force of each of the four load cells 150 associated with the left plate 130, designated as " $R_{Lci}$ ", or the Reaction Force of each of the four load cells 150 associated with the right plate 120, designated as " $R_{Rci}$ ", are added together to calculate the GRF for that side. These individual reaction forces and the GRF for each side are used to calculate the limb contact positions with respect to the X and Y-axes.

The X and Y limb contact positions are calculated by summing the moments in the X-axis and Y-axis directions. Specifically, the  $GRF_R$  and  $X_R$  and  $Y_R$  contact limb positions of the right plate are calculated as:

$$GRF_R = \sum_{i=1}^4 R_{Lci} \quad (1)$$

$$X_R = \frac{\sum_{i=1}^4 [X_{Lci} - R_{Lci}]}{\sum_{i=1}^4 R_{Lci}} \quad (2)$$

$$Y_R = \frac{\sum_{i=1}^4 [Y_{Lci} - R_{Lci}]}{\sum_{i=1}^4 R_{Lci}} \quad (3)$$

where  $R_{Lci}$  is the reaction force read by the i-th load cell, and  $X_{Lci}$  and  $Y_{Lci}$  are the X and Y coordinates of the load cells positions, as depicted in Figure 3. The corresponding GRF and limb positions of the left plate are calculated in a similar way:

$$GRF_L = \sum_{i=5}^8 R_{LCi} \quad (4)$$

$$x_L = \frac{\sum_{i=5}^8 [X_{LCi} - R_{LCi}]}{\sum_{i=1}^8 R_{LCi}} \quad (5)$$

$$y_L = \frac{\sum_{i=5}^8 [y_{LCi} - R_{LCi}]}{\sum_{i=5}^8 R_{LCi}} \quad (6)$$

The time history of the X and Y limb positions and the left and right GRF values for a sound cow that has passed through the device are depicted in Figure 3. The X and Y limb positions and the GRF values, shown in Figure 3, are used to calculate various limb movement variables, as discussed in greater detail below. These limb movement variables are analyzed to objectively determine whether an animal, such as a cow, has hoof, foot, or leg ailments. Analysis of these limb movement variables are the key to identifying lame animals and detecting which limb of an animal is afflicted with an ailment well before the ailment is manifested in a manner detectable by purely visual observation of the animal's movement. The limb movement variables are calculated by analyzing the X, Y and GRF values and the walking speed of each animal passing through the RFD system 100.

Various limb movement characteristics are calculated from the information depicted in Figure 6. Table 2 below lists the values of non-limiting limb movement variables:

- (i) normalized peak ground reaction force PRGF,
- (ii) impulse which is the integral of the normalized GRF with respect to time,
- (iii) stance time, the time during which a limb is in contact with the floor plate,
- (iv) normalized average ground reaction force AGRF which is the impulse divided by the stance time,
- (v) step size of individual limbs,

- 10507311-040501
- (vi) speed of animal movement when a particular limb contacts the floor,
  - (vii) the product of the impulse and cow speed which results in a characteristic unit length;
  - (viii) the "m-energy", defined herein as the integral of the magnitude of the GRFs with respect to the frequency in the frequency response domain;
  - (ix) the "p-energy", defined herein as the integral, over the frequency domain, of the product of the magnitude of the GRFs and frequency; and
  - (x) understep of the animal, for a left side or right side of the animal, such as a horse, defined as the Y position of the fore limb placement ( $Y_{FORE}$ ) minus the Y position of the hind limb placement ( $Y_{HIND}$ ), wherein a positive value indicates that the animal puts the front limb ahead of the rear limb as it moves through the RFD and wherein a negative value indicates that the animal puts the rear limb ahead of the front limb as it moves through the RFD.

Examples of the usefulness of these limb movement variables are illustrate in Figures 6 and 7. A full set of leg positions, X and Y values, and ground reaction forces, GRF values are plotted in Figure 6 for a healthy cow and in Figure 7 for a lame cow. The identification of the time, position, and intensity of individual front and rear limb contact with the left and right plates 130, 120 is premised, in part, on the fact that the left and right forelimbs strike the plate first and the hind limbs follow behind. Using this premise, the sequence by which the animal's limbs contacted the plates 130, 120 may be determined. Photocell 160 data is used to confirm the position of the cow and to verify that only one cow is on the force plates 130, 120. Limb movement variables, provided below, may be calculated when a single leg is in contact with the left or right plate or even when two limbs are in contact with a single plate. The typical RFD output consists of both single and two limb positions.

The stance time may be computer for a fore limb, a rear limb, or for both a fore and rear limb, or for all limbs. The total time that a limb is in contact with the left or right plate 130, 120 may be calculated by taking a difference between a first time at which an applied force from the

selected limb first exceeds a predetermined threshold force as the limb is applied to the plate and a second time at which the applied force from the limb falls below the predetermined threshold force. This defines a discrete force application event for the selected limb. In one aspect, the predetermined threshold is simply a force that is used as a trigger to start and stop the computation of the stance time. The preselected force is generally between 0.00 to about 5.0 lbf, but could be 10.0 lbf, 20.0 lbf, or higher, so long as a consistent value is used.

When only one limb is in contact with the plate 130, 120, the position of that leg is calculated by the computer 900 utilizing equations (1) through (6), above, and output to an appropriate output device, such as display 912 or attached printer, or to a remote device through communication interface 918. For example, Figure 6 shows a sound cow that has placed her right forelimb first at  $Y = 53$  cm (Figure 6(ii)(a)) and then her left forelimb at  $Y = 96$  cm (Figure 6(i)(b)). Next, the right hind limb is placed at  $Y = 8$  cm (Figure 6(ii)(c)) and the right forelimb was moved to  $Y = 155$  cm (Figure 6(ii)(d)).

Concurrent placement of both the right fore and hind limbs on the right plate 120 is represented in Figures 6(ii) and 6(iv) as "cd". Similarly, the left hind and fore limbs are then placed at  $Y = 46$  cm and  $Y = 193$  cm, respectively, as shown in Figures 6(i) and 6(iii). Concurrent placement of both the left fore and hind limbs on the left plate 130 is represented as "ef". At the end of the cow's walk-through, the right and left hind limbs were placed at  $Y = 107$  cm (Figure 6(ii)(g)) and  $Y = 163$  cm (Figure 6(i)(h)), respectively.

Normalized GRF values of the sound cow's left and right limbs are depicted in Figures 6(iii) and 6(iv), which illustrate that the peak GRF values of the right and left fore limbs are 0.55 (see Figure 6(iv)(a)) and 0.54 (see Figure 6(iii)(b)), respectively, whereas the peaks of the right and left hind limbs are 0.39 (see Figure 6(iv)(g)) and 0.41 (see Figure 6(iii)(h)), respectively.

The numerical values selected limb movement variables of sound cow 18 are listed in Table 2, below.

Table 2. Limb movement variables of sound cow 18.

Cow	Limb Movement Variables	Individual Limbs			
		Left Front [LF]	Right Front [RF]	Left Rear [LR]	Right Rear [RR]
Sound 18	Normalized PGRF	0.54	0.55	0.41	0.39
	Stance time (sec)	2.30	1.95	1.70	1.65
	Impulse (sec)	0.88	0.71	0.52	0.45
	Normalized AGRF	0.38	0.37	0.31	0.27
	Step size (cm)	99	101	115	101
	Speed of animal (cm/sec)	43	43	43	46
	Impulse * Speed (cm)	38	31	23	21

Similarly, Figure 7 depicts the Y coordinate and normalized GRF of a cow (lame cow 94) that is known to be lame as a result of sole bruising in her right rear limb. As shown by Figure 7, the lame cow first places her right front limb at Y = 46 cm (Figure 7(ii)(a)) and left front limb at Y = 97 cm (Figure 7(i)(b)). Subsequently the right and left rear limbs are placed at Y = 30 cm (Figure 7(ii)(c)) and Y = 64 cm (Figure 7(i)(d)), respectively. Then, the right front limb is placed at Y = 114 cm (Figure 7(ii)(e)) and the right plate 120 experiences two limb contact, designated as "ce" in Figure 7(ii). Finally, the left and right rear limbs were placed at Y = 198 cm (Figure 7(i)(g)) and Y = 127 cm (Figure 7(ii)(f)), respectively. The varying Y position reading (of 127 to 165 cm) when the right hind limb contacts the floor 120 illustrates a shift in the cow's weight placement toward the toe and off the heel.

Normalized GRF values of the lame cow's left and right limbs are depicted in Figures 7(iii) and 7(iv), which illustrate that the peak GRF values of the right and left fore limbs are 0.47 (see Figure 7(iv)(a)) and 0.53 (see Figure 7(iii)(b)), respectively, whereas the peaks of the right and left hind limbs are 0.12 (see Figure 7(iv)(g)) and 0.50 (see Figure 7(iii)(h)), respectively. Thus, the lame right hind limb produces a noticeably low peak GRF value.

The numerical values selected limb movement variables of lame cow 94 are listed in Table 3, below.

Table 3. Limb movement variables of lame cow 94.

Cow	Limb Movement Variables	Individual Limbs			
		Left Front [LF]	Right Front [RF]	Left Rear [LR]	Right Rear [RR]
Lame 94	Normalized PGRF	0.53	0.47	0.50	0.12
	Stance time (sec)	1.20	1.20	1.45	0.75
	Impulse (sec)	0.39	0.39	0.51	0.05
	Normalized AGRF	0.33	0.32	0.35	0.07
	Step size (cm)	NA	72	121	110
	Speed of animal (cm/sec)	97	89	56	56
	Impulse * Speed (cm)	38	35	29	3

Note the low values of normalized PGRF, impulse, AGRF, and the product of impulse and speed associated with the right rear limb of cow 94. Similar results were obtained in additional tests conducted on groups of sound cows and lame cows, as evident in the tables of test data presented in Figures 11 and 12.

When both the fore and rear limbs contact the plate, the RFD captures the position of the equivalent (resultant) applied load. These two limb positions and the corresponding equivalent loads are shown, for example, in Figures 8 (a), (b), (c), (d). This equivalent load can be decomposed into the loads of the individual limbs as explained below.

From the time history of the Y position before and after the two limb contact one skilled in the art can recognize the positions of the front (Y2) and rear limbs (Y1). In Figure 9(a), for

example, the left rear limb is placed at  $Y1 = 49$  cm and the left front limb is placed at  $Y2 = 190$  cm. At the point in time between approximately 7.5 seconds and 8.5 seconds, both the front limb and the rear limb are in contact with the left plate 130. Assuming no slip conditions in accord with the anti-slip component of the above-described aspects of the force plate 130, the value of  $Y1$  and  $Y2$  do not change and are known. Following a determination that two limbs are in contact with a force plate, such as the example shown in Figure 8(a), the GRF of the individual limbs may be calculated by solving the following two limb model presenting two equations with two unknowns:

$$F1 + F2 = \Sigma [R_{LCi}] \quad (7)$$

$$F1 * Y1 + F2 * Y2 = \Sigma [Y_{LCi} * R_{LCi}] \quad (8)$$

Where,  $i = 1$  to 4 for left and right plate load cells,  $R_{LCi}$  = load cell outputs,  $Y_{LCi}$  = load cell  $Y$  positions,  $F1$  = GRF of the rear limb and  $F2$  = GRF of the front limb. By solving these two limb model equations, the GRF of the individual limbs may be obtained as shown in Figure 8 (e) and 8 (f).

Furthermore, the limb movement variables can be used to evaluate the symmetry characteristics of the animal movement (e.g., walking, trotting, running, etc.) parameters. A symmetry factor ("SF") is expressed as:

$$SF = \frac{R_{LMV} - L_{LMV}}{R_{LMV} + L_{LMV}} \quad (9)$$

where  $R_{LMV}$  and  $L_{LMV}$  correspond to right and left limb movement variables. A zero SF value represents a symmetric condition whereas positive and negative values represent dominance of the right and left sides, respectively. In the extreme case where a limb movement variable approaches a zero value, SF converges to 1.0 when the left limb is lame, and -1.0 when the right limb is lame. Hence, SF is an intensity indicator of lameness that utilizes the bilateral symmetry of the animal's body to examine the extent to which a selected left or right limb

movement variable differs from the corresponding value of its counter side. Table 4 lists the SF values of the limb movement variables of the sound cow of Figure 6 and the lame cow of Fig. 7.

Table 4. The SF values of the limb movement variables of cows 18 and 94.

Limb Movement Variables	Cow 18 - Sound		Cow 94 - Lame	
	Symmetry of Front limbs	Symmetry of Rear limbs	Symmetry of Front limbs	Symmetry of Rear limbs
Normalized PGRF	0.01	-0.03	-0.06	-0.61
Stance time	-0.08	-0.02	0.00	-0.32
Impulse	-0.11	-0.07	0.00	-0.82
Normalized AGRF	-0.01	-0.07	-0.02	-0.60
Step size	0.01	-0.07	NA	-0.05
Speed of animal	0.00	0.03	-0.04	0.00
Impulse * Speed	-0.10	-0.05	-0.04	-0.81

Note the low SF values (less than 0.11) of the sound cow 18, and the high values (as high as 0.82) of the lame cow 94. These measurements are indicative of still further diagnostic benefits afforded by the method and apparatus of the present invention by identification and analysis of precursors to lameness, such as but not limited to various SF indicators, PGRF, Impulse, AGRF, and Impulse\*Speed. Present test data does not seem to indicate that step size and speed are significantly affected by early stages of lameness. However, such correlation has not conclusively been ruled out and may be determinable upon a sufficient sample population in accord with the present invention.

The RFD system 100 was further tested on three sound cows and three lame cows. Figure 9 depicts the test results as normalized PGRF and symmetry factor bar charts. Figure 9(i) depicts the normalized PGRF values of sound cows (cows 18, 130, and 136), wherein the typical values of 0.5 for the front limbs and 0.4 for the rear. The corresponding PGRF values for the

three lame cows (cows 94, 113, and 982), shown in Figure 9(ii), are 0.12 (right rear limb), 0.24 (left rear limb), and 0.25 (right rear limb). Figure 9(iii) and 9(iv) further depict the symmetry factors of the front and rear limbs. In accord with other test results, the SF values for the sound cows 18, 130, and 136, are better than 0.07, whereas the SF values of cows 94, 113, and 982 are -0.61, 0.33, and -0.30, respectively.

As noted previously, various conventional lameness detection schemes employ visual observations of the animal's posture or gait to obtain relatively assign a value corresponding to the severity of the lameness. In an effort to objectively characterize the status or severity of hoof and leg ailments (e.g., lameness), the present invention advantageously determines various limb movement characteristics through the RFD system. The RFD system can be used to measure multiple variables representative of limb movements, such as: (a) peak value of ground reaction force (GRF) of individual limbs, (b) integral of GRF with respect to time, (c) stance time, (d) average GRF, (e) step size, (f) integral of the Fourier transformation of the GRF signature with respect to frequency, and (g) the integral with respect to frequency of the Fourier transform of the GRF signature multiplied by the frequency, (h) various symmetry variables, and numerous other combinations, derivatives, and integrals. To allow comparisons among different cows, the variables representative of limb movements may be normalized with respect to body weight and symmetry variables may be used to compare left to right limbs for the same speed of body movement.

Additionally, just as the limb movement variables can be used to evaluate the symmetry characteristics of the animal walking parameters, for example, the limb movement variables may be advantageously used to actually relate clinical lameness diagnoses of individual limbs to the measured values of limb movement variables. As previously noted, the conventional techniques utilize subjective and non-quantitative visual observation. In accord with the inventive method, a statistically sufficient sample population of a selected animal, such as a dairy cow or horse, for example, is evaluated using the RFD to obtain limb movement variables for each animal. Subsequent to or preceding the RFD testing on the sample population, a determination is made

by a veterinarian or other person trained to diagnose lameness, or other ailment or condition manifesting in the animal's movement.

With this knowledge of the actual physical condition of each animal, correlations may be drawn between individual limb variables or combinations of limb variables such as but not limited to any data manipulation, such as but not limited to products, sums, differences, dividends, derivatives, integrals, log charts, etc., conventionally used to relate data to definable patterns used to then generate a function to describe an observed phenomena such that a function of one or more variables may be established between the limb movement data, limb movement variables, and/or combinations thereof, and lameness, for example. Moreover, it is within the scope of the invention to perform one or more additional RFD tests (e.g., a "subsequent" test) immediately or soon after completion of a successful first test. This subsequent test may be used to validate or confirm the results of the first test, particularly when the first test indicates the onset of a potential problem with the animal.

In this manner, the invention is not limited to simple determinations of "sound" or "lame", but is capable of measuring and defining many levels or degrees of lameness, which facilitates early detection of potential lameness precursors and thereby promotes animal well-being. In accord with the invention, inventors have performed logistic regression and discriminant analyses, such as by LOGISTIC™, STEPDISC™, and SAS™ computer program subroutines, known to those skilled in the statistical analysis art, to determine a strong correlation between the visual lameness scoring scale and the GRFs determined by the apparatus of the invention. Specifically, the correlation between the visual lameness scoring scale and the GRFs can be captured by the average GRF values ( $p < 0.05$ ), or in other words, a 95% confidence level, of individual limbs. The model or formulas generatable therefrom, such as but not limited to an estimated lameness index derived as the weighted sum of these probabilities, predict probabilities that a cow is sound, mildly lame, and lame. Further, it is to be appreciated that the models or formulas generated from the data obtained by the RFD system may include many degrees of lameness, or other observed characteristic, in accord with a statistically significant sample size.

For example, 5 degrees of lameness, or even 10 or more degrees of lameness may be gleaned from sufficient data samples. The inventors have determined, with respect to a small sample size of 16 mildly lame and sound dairy cows, that the diagnostic results of the visual scoring scale and the new estimated lameness index matched perfectly for lame cows and the visual scores and lameness index of 2 out of 16 mildly lame and sound cases exhibited discrepancies. Thus, above example provides one instance wherein the limb movement data, limb movement variables, and mathematically manipulated combinations or variations thereof can be used to develop objective measures of dairy cow lameness in combination with existing clinical lameness diagnoses of individual limbs. However, it is to be understood that the limb movement data, limb movement variables, and mathematically manipulated combinations or variations thereof can be used to develop many other objective measures of dairy cow lameness or other characteristics of interest in combination with existing clinical lameness diagnoses of individual limbs and these objective measures could include many levels of severity or interest.

In one aspect of the invention, therefore, models for an ailment, such as lameness, as varying degrees of severity thereof, may be developed for specific animal-types based on the data obtained by the RFD. Such models could thus determine the lameness score of individual limbs based on the values of a set of important limb movement variables and could account for many environmental variables such as geographic location, climate, living conditions, and even farm management styles.

In still another aspect of the invention, following development of correlations between the raw data and/or derived data, as noted above, obtained from the RFD system, the RFD system can be largely or entirely automatized. For example, an RFD system could be placed in a tract that the animals pass through with a frequency commensurate with at least a desired diagnostic frequency and the system may be set up and calibrated in advance. As previously noted, trending data of the RFD system calibration may be used to determine whether or not a particular application or environment of the RFD system would permit re-calibrations at a frequency less than the diagnostic test frequency. In such automatic operation, if the computer

carry digital data streams. The signals through the various networks and the signals on network link 920 and through communication interface 918, which carry the digital data to and from computer system 900, are exemplary forms of carrier waves transporting the information. Thus the processing required by method of the invention described by way of example herein may be implemented on a local computer utilizing storage device 910 or may be implemented, for example, on a LAN or over the internet.

Computer system 900 can send messages and receive data, including program code, through the network(s), network link 920, and communication interface 918. In the Internet example, a server 930 might transmit a requested code for an application program through Internet 928, ISP 926, local network 922 and communication interface 918. The received code may be executed by processor 904 as it is received, and/or stored in storage device 910, or other non-volatile storage for later execution. In this manner, computer system 900 may obtain application code in the form of a carrier wave.

While this invention has been described in connection with what is presently considered to be the most practical and preferred embodiment, it is to be understood that the invention is not limited to the disclosed aspects of the invention, but on the contrary, is intended to cover various modifications and equivalent arrangements included within the spirit and scope of the appended claims and may include modifications to such as, but not limited to, modification of the force plate geometry and adjustment of the number and placement of load cells to accommodate the monitored activity.
